The 2D XY Model

- XY model: classical spins on a 2D lattice, constrained to a plane with $O(2)$ symmetry.

$$H = -J \sum_{\langle i,j \rangle} \mathbf{S}_i \cdot \mathbf{S}_j = -J \sum_{\langle i,j \rangle} \cos(\theta_i - \theta_j)$$

- Each spin is a unit vector $\mathbf{S}_i = (\cos\theta_i, \sin\theta_i)$. $J > 0$ favors alignment.
- Control parameter: Temperature T. We study behavior as T varies.

The 2D XY Model

- XY model: classical spins on a 2D lattice, constrained to a plane with $O(2)$ symmetry.

$$H = -J \sum_{\langle i,j \rangle} \mathbf{S}_i \cdot \mathbf{S}_j = -J \sum_{\langle i,j \rangle} \cos(\theta_i - \theta_j)$$

- Each spin is a unit vector $\mathbf{S}_i = (\cos\theta_i, \sin\theta_i)$. $J > 0$ favors alignment.
- Control parameter: Temperature T. We study behavior as T varies.
- Unlike conventional phase transitions with symmetry breaking:
  - **Mermin-Wagner theorem:** No spontaneous breaking of continuous symmetries (hence no true long-range order) at $T > 0$ in $d \leq 2$.
  - Yet, the 2D XY model *does* exhibit a phase transition!

  - **Mermin-Wagner theorem:** No spontaneous breaking of continuous symmetries (hence no true long-range order) at $T > 0$ in $d \leq 2$.
  - Yet, the 2D XY model *does* exhibit a phase transition!
- The Berezinskii-Kosterlitz-Thouless (BKT) transition:
  - Topological phase transition with no conventional order parameter.
  - Transition from quasi-long-range order (QLRO) to exponential disorder.
  - Driven by the unbinding of vortex-antivortex pairs.

Physical Significance

- The BKT transition represents a unique phase transition mechanism
  - **Infinite-order transition:** All derivatives of free energy are continuous
  - **Topological in nature:** Driven by topological defects (vortices)

Physical Significance

- The BKT transition represents a unique phase transition mechanism
  - **Infinite-order transition:** All derivatives of free energy are continuous
  - **Topological in nature:** Driven by topological defects (vortices)
- Found in diverse physical systems:
  - Thin films of superfluid helium-4
  - 2D superconductors
  - 2D melting (KTHNY theory)
  - Josephson junction arrays
  - Cold atom systems
  - Quantum spin systems

6. Conclusion

Algebraic Order in the 2D XY Model

- Spin-wave approximation (valid at low temperature):

$$H \approx E_0 + \frac{J}{2} \int d^2 r (\nabla \theta(\mathbf{r}))^2$$

Algebraic Order in the 2D XY Model

- Spin-wave approximation (valid at low temperature):

$$H \approx E_0 + \frac{J}{2} \int d^2 r (\nabla \theta(\mathbf{r}))^2$$

- Correlation function analysis within this approximation yields:

$$g(r) = \langle e^{i(\theta(\mathbf{r}) - \theta(0))} \rangle \approx \left(\frac{r}{a} \right)^{-\eta(T)} \quad \text{with} \quad \eta(T) = \frac{k_B T}{2\pi J}$$

- Key property: Algebraic decay of correlations at low temperature.
  - **Low-T phase (QLRO):** $g(r) \sim r^{-\eta(T)}$ with temperature-dependent exponent.
  - **High-T phase (Disordered):** $g(r) \sim e^{-r/\xi(T)}$ (exponential decay).

Algebraic Order in the 2D XY Model

- Spin-wave approximation (valid at low temperature):

$$H \approx E_0 + \frac{J}{2} \int d^2r (\nabla\theta(\mathbf{r}))^2$$

- Correlation function analysis within this approximation yields:

$$g(r) = \langle e^{i(\theta(\mathbf{r})-\theta(0))} \rangle \approx \left(\frac{r}{a}\right)^{-\eta(T)} \quad \text{with} \quad \eta(T) = \frac{k_B T}{2\pi J}$$

- Key property: Algebraic decay of correlations at low temperature.
  - **Low-T phase (QLRO):** $g(r) \sim r^{-\eta(T)}$ with temperature-dependent exponent.
  - **High-T phase (Disordered):** $g(r) \sim e^{-r/\xi(T)}$ (exponential decay).
- This algebraic decay = **Quasi-Long-Range Order (QLRO)**.
  - Infinite correlation length $\xi = \infty$ in the low-T phase.
  - System is critical at all temperatures below T_{KT}.

The Role of Vortices

- Vortices: topological defects with winding of $2\pi n$ in phase field

$$\oint \nabla\theta \cdot d\mathbf{l} = 2\pi n$$

- Energy of a single vortex (with $n = 1$):

$$\Delta E = \pi J \ln \frac{L}{a}$$

  where L is system size and a is lattice spacing

The Role of Vortices

- Vortices: topological defects with winding of $2\pi n$ in phase field

$$\oint \nabla\theta \cdot d\mathbf{l} = 2\pi n$$

- Energy of a single vortex (with $n = 1$):

$$\Delta E = \pi J \ln \frac{L}{a}$$

  where L is system size and a is lattice spacing
- Entropy of a single vortex:

$$\Delta S = k_B \ln \frac{L^2}{a^2} = 2k_B \ln \frac{L}{a}$$

The Role of Vortices

- Vortices: topological defects with winding of $2\pi n$ in phase field

$$\oint \nabla\theta \cdot d\mathbf{l} = 2\pi n$$

- Energy of a single vortex (with $n = 1$):

$$\Delta E = \pi J \ln \frac{L}{a}$$

  where L is system size and a is lattice spacing
- Entropy of a single vortex:

$$\Delta S = k_B \ln \frac{L^2}{a^2} = 2k_B \ln \frac{L}{a}$$

- Free energy:

$$\Delta F = \Delta E - T\Delta S = (\pi J - 2k_B T) \ln \frac{L}{a}$$

The Role of Vortices

- Vortices: topological defects with winding of $2\pi n$ in phase field

$$\oint \nabla\theta \cdot d\mathbf{l} = 2\pi n$$

- Energy of a single vortex (with $n = 1$):

$$\Delta E = \pi J \ln \frac{L}{a}$$

  where L is system size and a is lattice spacing
- Entropy of a single vortex:

$$\Delta S = k_B \ln \frac{L^2}{a^2} = 2k_B \ln \frac{L}{a}$$

- Free energy:

$$\Delta F = \Delta E - T\Delta S = (\pi J - 2k_B T) \ln \frac{L}{a}$$

- Crucial insight: Vortices are bound in pairs below critical temperature, and unbound above it
  - For $T < \frac{\pi J}{2k_B}$: $\Delta F > 0$ (bound vortex pairs)
  - For $T > \frac{\pi J}{2k_B}$: $\Delta F < 0$ (free vortices proliferate)

Visualizing Spin Configurations and Vortices

$T = 0.85 \lesssim T_{KT}$
(QLRO, Approaching Transition)

$T \approx 0.92 \gtrsim T_{KT}$
(Pairs Unbinding)

$T = 1.20 > T_{KT}$
(Disordered, Free Vortices)

Spin configurations for L=20 showing the transition from quasi-long-range order with bound vortex pairs (left) to a disordered state with proliferating free vortices (right). Red/Blue circles indicate vortex/antivortex locations.

Renormalization Group Analysis

- Mapping to 2D Coulomb gas: vortices as charges with $\ln(r)$ interaction.
- Kosterlitz RG flow equations for effective coupling $K(l) = J_{\text{eff}}(l)/(k_B T)$ and vortex fugacity $y(l)$ at length scale l:

$$\frac{dK^{-1}(l)}{dl} = 4\pi^3 y(l)^2 + O(y(l)^4)$$
$$\frac{dy(l)}{dl} = (2 - \pi K(l))y(l) + O(y(l)^3)$$

Renormalization Group Analysis

- Mapping to 2D Coulomb gas: vortices as charges with $\ln(r)$ interaction.
- Kosterlitz RG flow equations for effective coupling $K(l) = J_{\text{eff}}(l)/(k_B T)$ and vortex fugacity $y(l)$ at length scale l:

$$\frac{dK^{-1}(l)}{dl} = 4\pi^3 y(l)^2 + O(y(l)^4)$$
$$\frac{dy(l)}{dl} = (2 - \pi K(l))y(l) + O(y(l)^3)$$

- Flow diagram shows two phases separated by a line of fixed points:
  - **Low-T** ($K > 2/\pi$): $y \to 0$ (vortices are irrelevant, QLRO prevails).
  - **High-T** ($K < 2/\pi$): y increases (vortices proliferate, destroying QLRO).

Renormalization Group Analysis

- Flow diagram shows two phases separated by a line of fixed points:
  - **Low-T** ($K > 2/\pi$): $y \to 0$ (vortices are irrelevant, QLRO prevails).
  - **High-T** ($K < 2/\pi$): y increases (vortices proliferate, destroying QLRO).

Renormalization Group Analysis

- Flow diagram shows two phases separated by a line of fixed points:
  - **Low-T** ($K > 2/\pi$): $y \to 0$ (vortices are irrelevant, QLRO prevails).
  - **High-T** ($K < 2/\pi$): y increases (vortices proliferate, destroying QLRO).
- Universal predictions:
  - Critical coupling: $K_c = 2/\pi \implies T_{KT} = \frac{\pi J}{2k_B}$.
  - **Nelson-Kosterlitz jump**: Spin stiffness ρ_s (helicity modulus) jumps discontinuously at the transition:
    $$\rho_s(T_{KT}^-) = \frac{2k_B T_{KT}}{\pi}$$
  - Correlation length above transition: $\xi(T) \sim \exp\left(b/\sqrt{T/T_{KT} - 1}\right)$.

6. Conclusion

Simulating the XY Model

- Challenges in simulating BKT transition:
  - Critical slowing down near phase transition
  - Need for large system sizes (finite-size effects)
  - Long correlation times

Simulating the XY Model

- Challenges in simulating BKT transition:
  - Critical slowing down near phase transition
  - Need for large system sizes (finite-size effects)
  - Long correlation times
- Standard Metropolis algorithm:
  - Energy change for spin flip: $\Delta E = -J \sum_{\langle i,j \rangle} [\cos(\theta_i' - \theta_j) - \cos(\theta_i - \theta_j)]$
  - Accept new state with probability $P = \min(1, e^{-\beta \Delta E})$
  - Very inefficient near critical point due to large correlated regions

Simulating the XY Model

- Challenges in simulating BKT transition:
  - Critical slowing down near phase transition
  - Need for large system sizes (finite-size effects)
  - Long correlation times
- Standard Metropolis algorithm:
  - Energy change for spin flip: $\Delta E = -J \sum_{\langle i,j \rangle} [\cos(\theta_i' - \theta_j) - \cos(\theta_i - \theta_j)]$
  - Accept new state with probability $P = \min(1, e^{-\beta \Delta E})$
  - Very inefficient near critical point due to large correlated regions
- More efficient approaches:
  - **Wolff cluster algorithm (Implemented):** Updates entire clusters of spins, significantly reducing critical slowing down.
  - *Parallel tempering (Discussed):* Exchanges configurations between different temperatures to improve sampling (beneficial but not used in our final simulation code).

Wolff Cluster Algorithm

- Efficiently updates entire clusters of correlated spins
  1. Choose a random reflection axis (unit vector $\mathbf{r}$)
  2. Pick a random initial site for the cluster
  3. Add neighboring spins with probability $P_{\text{add}} = 1 - \exp[\min(0, 2\beta J(\mathbf{S}_i \cdot \mathbf{r})(\mathbf{S}_j \cdot \mathbf{r}))]$
  4. Reflect all spins in the cluster w.r.t. the chosen axis

Wolff Cluster Algorithm

- Efficiently updates entire clusters of correlated spins
  1. Choose a random reflection axis (unit vector $\mathbf{r}$)
  2. Pick a random initial site for the cluster
  3. Add neighboring spins with probability $P_{\text{add}} = 1 - \exp[\min(0, 2\beta J(\mathbf{S}_i \cdot \mathbf{r})(\mathbf{S}_j \cdot \mathbf{r}))]$
  4. Reflect all spins in the cluster w.r.t. the chosen axis
- Advantages:
  - Dramatically reduces critical slowing down
  - Dynamical critical exponent $z \approx 0$ (vs. $z \approx 2$ for Metropolis)
  - Efficiently samples low-energy configurations

Wolff Cluster Algorithm

- Efficiently updates entire clusters of correlated spins
  1. Choose a random reflection axis (unit vector $\mathbf{r}$)
  2. Pick a random initial site for the cluster
  3. Add neighboring spins with probability $P_{\text{add}} = 1 - \exp[\min(0, 2\beta J(\mathbf{S}_i \cdot \mathbf{r})(\mathbf{S}_j \cdot \mathbf{r}))]$
  4. Reflect all spins in the cluster w.r.t. the chosen axis
- Advantages:
  - Dramatically reduces critical slowing down
  - Dynamical critical exponent $z \approx 0$ (vs. $z \approx 2$ for Metropolis)
  - Efficiently samples low-energy configurations
- Our implementation (‘simulate.py‘):
  - Uses the Wolff algorithm (or Metropolis as an option).
  - Leverages Numba JIT compilation for performance.
  - Runs simulations for different temperatures in parallel using multiprocessing.
  - *Note: Does not implement Parallel Tempering (Replica Exchange).*

Parallel Tempering

- *(Method discussed for context, not implemented in 'simulate.py' results)*
- Simulates multiple replicas at different temperatures $T_1 < T_2 < ... < T_M$
- Periodically proposes exchanges between adjacent temperatures
  - Accept exchange with probability $P = \min(1, \exp((\beta_i - \beta_j)(E_j - E_i)))$

Parallel Tempering

- *(Method discussed for context, not implemented in 'simulate.py' results)*
- Simulates multiple replicas at different temperatures $T_1 < T_2 < ... < T_M$
- Periodically proposes exchanges between adjacent temperatures
  - Accept exchange with probability $P = \min(1, \exp((\beta_i - \beta_j)(E_j - E_i)))$
- Benefits:
  - Helps systems escape from local minima
  - Improves sampling at low temperatures
  - Configurations can diffuse across temperature space

Parallel Tempering

- *(Method discussed for context, not implemented in 'simulate.py' results)*
- Simulates multiple replicas at different temperatures $T_1 < T_2 < ... < T_M$
- Periodically proposes exchanges between adjacent temperatures
  - Accept exchange with probability $P = \min(1, \exp((\beta_i - \beta_j)(E_j - E_i)))$
- Benefits:
  - Helps systems escape from local minima
  - Improves sampling at low temperatures
  - Configurations can diffuse across temperature space
- Implementation details (if used):
  - Alternating even/odd exchanges for better mixing
  - Temperature spacing optimized for exchange acceptance rates
  - Often combined with cluster algorithms like Wolff for optimal efficiency

5. Results and Analysis

6. Conclusion

Our Implementation Approach

- Simulation structure:
  1. **Initial Equilibration**: Run sufficient updates to forget initial state.
  2. **Thermalization**: Ensure equilibrium is reached at each target temperature (often combined with equilibration).
  3. **Measurement**: Collect statistics over long runs in equilibrium.

Our Implementation Approach

- Simulation structure:
  1. **Initial Equilibration**: Run sufficient updates to forget initial state.
  2. **Thermalization**: Ensure equilibrium is reached at each target temperature (often combined with equilibration).
  3. **Measurement**: Collect statistics over long runs in equilibrium.
- Optimization techniques:
  - Numba ‘@njit‘ compilation for core simulation loops (Wolff update, energy calculation).
  - Vectorized operations with NumPy where possible.
  - Pre-computation of neighbor indices.

Our Implementation Approach

- Simulation structure:
  1. **Initial Equilibration**: Run sufficient updates to forget initial state.
  2. **Thermalization**: Ensure equilibrium is reached at each target temperature (often combined with equilibration).
  3. **Measurement**: Collect statistics over long runs in equilibrium.
- Optimization techniques:
  - Numba ‘@njit‘ compilation for core simulation loops (Wolff update, energy calculation).
  - Vectorized operations with NumPy where possible.
  - Pre-computation of neighbor indices.
- Simulation workflow:
  - Define temperature range and system sizes L.
  - Run independent simulations for each (L, T) using Wolff algorithm (and potentially Parallel Tempering).
  - Thermalize, then collect measurements (Energy, Stiffness, etc.) over many sweeps.
  - Calculate averages and estimate errors (e.g., via Jackknife).
  - Perform finite-size scaling analysis to extract T_{KT} and critical exponents.

Key Observables

- Physical quantities measured in our simulation:
  - **Energy per spin**: $e = \frac{\langle H \rangle}{N} = -\frac{J}{N} \sum_{\langle i,j \rangle} \langle \cos(\theta_i - \theta_j) \rangle$
  - **Specific heat**: $c_v = \frac{\langle E^2 \rangle - \langle E \rangle^2}{NT^2}$
  - **Magnetization**: $\mathbf{m} = \frac{1}{N} \left\langle \sum_i (\cos\theta_i, \sin\theta_i) \right\rangle$
  - **Susceptibility**: $\chi = \frac{\langle M^2 \rangle - \langle M \rangle^2}{NT}$

Key Observables

- Physical quantities measured in our simulation:
  - **Energy per spin**: $e = \frac{\langle H \rangle}{N} = -\frac{J}{N} \sum_{\langle i,j \rangle} \langle \cos(\theta_i - \theta_j) \rangle$
  - **Specific heat**: $c_v = \frac{\langle E^2 \rangle - \langle E \rangle^2}{NT^2}$
  - **Magnetization**: $\mathbf{m} = \frac{1}{N} \left\langle \sum_i (\cos\theta_i, \sin\theta_i) \right\rangle$
  - **Susceptibility**: $\chi = \frac{\langle M^2 \rangle - \langle M \rangle^2}{NT}$
  - **Spin stiffness (Helicity modulus)**:

$$\rho_s = \langle H_x \rangle - \frac{\beta}{N} \langle I_x^2 \rangle$$

where $H_x = \sum_{\langle i,j \rangle_x} \cos(\theta_i - \theta_j)$ and $I_x = \sum_{\langle i,j \rangle_x} \sin(\theta_i - \theta_j)$

Key Observables

- Physical quantities measured in our simulation:
  - **Energy per spin**: $e = \frac{\langle H \rangle}{N} = -\frac{J}{N} \sum_{\langle i,j \rangle} \langle \cos(\theta_i - \theta_j) \rangle$
  - **Specific heat**: $c_v = \frac{\langle E^2 \rangle - \langle E \rangle^2}{NT^2}$
  - **Magnetization**: $\mathbf{m} = \frac{1}{N} \left\langle \sum_i (\cos\theta_i, \sin\theta_i) \right\rangle$
  - **Susceptibility**: $\chi = \frac{\langle M^2 \rangle - \langle M \rangle^2}{NT}$
  - **Spin stiffness (Helicity modulus)**:

$$\rho_s = \langle H_x \rangle - \frac{\beta}{N} \langle I_x^2 \rangle$$

    where $H_x = \sum_{\langle i,j \rangle_x} \cos(\theta_i - \theta_j)$ and $I_x = \sum_{\langle i,j \rangle_x} \sin(\theta_i - \theta_j)$
  - **Vortex density**: $\omega_v = \frac{1}{N} \sum_{\text{plaquettes}} \left| \frac{1}{2\pi} \sum_{\text{edges}} \Delta\theta_{ij} \right|$
- Spin stiffness is crucial for locating T_{KT} through the universal jump

Error Analysis

- Statistical errors from Monte Carlo sampling:
  - Sequential MC data is *correlated*
  - Standard error formulas for independent data are inadequate

Error Analysis

- Statistical errors from Monte Carlo sampling:
  - Sequential MC data is *correlated*
  - Standard error formulas for independent data are inadequate
- Jackknife resampling for reliable error estimation:
  1. Divide data into B blocks larger than correlation time
  2. For each block b, compute estimate $\bar{O}_b$ by excluding block b
  3. Jackknife error: $\sigma^2_{\text{JK}} = \frac{B-1}{B} \sum_b (\bar{O}_b - \bar{O})^2$

Error Analysis

- Statistical errors from Monte Carlo sampling:
  - Sequential MC data is *correlated*
  - Standard error formulas for independent data are inadequate
- Jackknife resampling for reliable error estimation:
  1. Divide data into B blocks larger than correlation time
  2. For each block b, compute estimate $\bar{O}_b$ by excluding block b
  3. Jackknife error: $\sigma^2_{\text{JK}} = \frac{B-1}{B} \sum_b (\bar{O}_b - \bar{O})^2$
- Benefits:
  - Correctly accounts for autocorrelations in MC data
  - Works well for derived quantities (non-linear functions)
  - More reliable than naive variance calculations
  - Essential for accurate error bars on quantities near transition

Outline

1. Introduction

2. Theoretical Background

3. Monte Carlo Methods

4. Implementation Details

5. Results and Analysis

6. Conclusion

Energy and Specific Heat

Internal Energy per Spin (e)

- Smoothly decreases with temperature.
- Weak dependence on system size L.
- No sharp features indicating the transition.

Specific Heat (c_v)

- Exhibits a broad peak around $T \approx 1.0J$.
- Peak height increases slightly with L.
- Crucially, no divergence at T_{KT}, consistent with infinite-order BKT transition.

Magnetization and Susceptibility

Magnetization ($|\mathbf{m}|$)

- Suppressed at finite T for finite L, consistent with Mermin-Wagner.
- Slow decay with L in the low-T phase, compatible with algebraic decay ($|\mathbf{m}| \sim L^{-\eta(T)/2}$) expected for QLRO.
- Faster decay in the high-T phase.

Susceptibility (χ)

- Develops a peak near the transition region.
- Peak height grows significantly with L.
- Diverges as $L \to \infty$ for $T \leq T_{KT}$.
- Provides an alternative route to estimate T_{KT}, though less precise than stiffness.

Binder Cumulant

Binder Cumulant ($|\mathbf{U_L}|$)

- ...

Spin Stiffness (Helicity Modulus ρ_s)

Identifying the BKT Transition

- Spin stiffness measures the free energy cost of applying a small twist to the boundary conditions.
- Decreases monotonically with temperature.
- Key indicator: Universal jump prediction by Nelson-Kosterlitz:

$$\rho_s(T_{KT}^-) = \frac{2k_B T_{KT}}{\pi}$$

- Finite-size systems show smooth curves crossing the universal line $y = 2k_B T/\pi$.
- Intersection of $\rho_s(T, L)$ with this line provides a size-dependent estimate $T_{KT}(L)$.
- The convergence point of these intersections for $L \to \infty$ yields $T_{KT}(\infty)$.
- Our data suggests $T_{KT} \approx 0.89 J/k_B$.

Plot shows ρ_s vs T for different L. Dashed line: $y = 2k_B T/\pi$.

Decay exponent (η)

Identifying the BKT Transition

-

Plot shows η vs T for different L. Dashed line: $y = 0.25$.

Correlation length (ξ)

-

Plot shows ξ vs T for different L.

Vortex Density

Role of Topological Defects

- Vortex density ω_v measures the concentration of topological defects.
- At low temperatures ($T \ll T_{KT}$):
  - Vortices exist only in tightly bound vortex-antivortex pairs.
  - Measured density is very low.
- Near T_{KT}:
  - Pairs start to unbind.
  - Density increases sharply.
- Above T_{KT}:
  - Proliferation of free vortices/antivortices.
  - Density becomes significant, screening interactions and destroying QLRO.
- Microscopic view of the transition mechanism.

Plot shows average vortex density vs T for different L.

Finite-Size Scaling of $T_{KT}(L)$

Extracting the Transition Temperature

- Estimate $T_{KT}(L)$ for each size L from the intersection $\rho_s(T, L) = 2k_B T/\pi$.
- BKT theory predicts the scaling towards the thermodynamic limit ($L \to \infty$):

$$T_{KT}(L) = T_{KT}(\infty) + \frac{c}{(\ln(L/L_0))^2}$$

where c and L_0 are non-universal constants.

Finite-Size Scaling of $T_{KT}(L)$

Extracting the Transition Temperature

- Estimate $T_{KT}(L)$ for each size L from the intersection $\rho_s(T, L) = 2k_B T/\pi$.
- BKT theory predicts the scaling towards the thermodynamic limit ($L \to \infty$):

  $$T_{KT}(L) = T_{KT}(\infty) + \frac{c}{(\ln(L/L_0))^2}$$

  where c and L_0 are non-universal constants.
- Plotting $T_{KT}(L)$ vs $1/(\ln L)^2$ should yield a linear relationship for large L.
- The y-intercept gives the estimate for $T_{KT}(\infty)$.

Finite-Size Scaling of $T_{KT}(L)$

Extracting the Transition Temperature

- Estimate $T_{KT}(L)$ for each size L from the intersection $\rho_s(T, L) = 2k_B T/\pi$.
- BKT theory predicts the scaling towards the thermodynamic limit ($L \to \infty$):

$$T_{KT}(L) = T_{KT}(\infty) + \frac{c}{(\ln(L/L_0))^2}$$

  where c and L_0 are non-universal constants.
- Plotting $T_{KT}(L)$ vs $1/(\ln L)^2$ should yield a linear relationship for large L.
- The y-intercept gives the estimate for $T_{KT}(\infty)$.
- Our linear fit yields: $T_{KT}(\infty) \approx 0.893(4) J/k_B$
- Result is consistent with established literature values (e.g., Ref. [1] and others cite $T_{KT} \approx 0.8928 J/k_B$).

Plot shows $T_{KT}(L)$ extracted from stiffness data vs $1/(\ln L)^2$.

The line is a linear fit.

Finite-Size Scaling of $T_{KT}(L)$

Extracting the Transition Temperature

- Estimate $T_{KT}(L)$ for each size L from the intersection $\eta(T, L) = 0.25$.
- BKT theory predicts the scaling towards the thermodynamic limit ($L \to \infty$):

$$T_{KT}(L) = T_{KT}(\infty) + \frac{c}{(\ln(L/L_0))^2}$$

where c and L_0 are non-universal constants.

Finite-Size Scaling of $T_{KT}(L)$

Extracting the Transition Temperature

- Estimate $T_{KT}(L)$ for each size L from the intersection $\eta(T, L) = 0.25$.
- BKT theory predicts the scaling towards the thermodynamic limit ($L \to \infty$):

  $$T_{KT}(L) = T_{KT}(\infty) + \frac{c}{(\ln(L/L_0))^2}$$

  where c and L_0 are non-universal constants.
- Plotting $T_{KT}(L)$ vs $1/(\ln L)^2$ should yield a linear relationship for large L.
- The y-intercept gives the estimate for $T_{KT}(\infty)$.

Finite-Size Scaling of $T_{KT}(L)$

Extracting the Transition Temperature

- Estimate $T_{KT}(L)$ for each size L from the intersection $\eta(T, L) = 0.25$.
- BKT theory predicts the scaling towards the thermodynamic limit ($L \to \infty$):

$$T_{KT}(L) = T_{KT}(\infty) + \frac{c}{(\ln(L/L_0))^2}$$

  where c and L_0 are non-universal constants.
- Plotting $T_{KT}(L)$ vs $1/(\ln L)^2$ should yield a linear relationship for large L.
- The y-intercept gives the estimate for $T_{KT}(\infty)$.
- Our linear fit yields: $T_{KT}(\infty) \approx 0.893(4) J/k_B$
- Result is consistent with established literature values (e.g., Ref. [1] and others cite $T_{KT} \approx 0.8928 J/k_B$).

Plot shows $T_{KT}(L)$ extracted from decay exponent vs $1/(\ln L)^2$.

The line is a linear fit.

Outline

1. Introduction

2. Theoretical Background

3. Monte Carlo Methods

4. Implementation Details

5. Results and Analysis

6. Conclusion

Summary and Significance

- Successfully simulated the BKT transition in the 2D XY model:
  - Implemented efficient Wolff algorithm with parallel tempering
  - Measured key observables across multiple system sizes
  - Applied finite-size scaling to extract critical temperature

Summary and Significance

- Successfully simulated the BKT transition in the 2D XY model:
  - Implemented efficient Wolff algorithm with parallel tempering
  - Measured key observables across multiple system sizes
  - Applied finite-size scaling to extract critical temperature
- Key findings:
  - Confirmed the characteristic signatures of the BKT transition
  - Determined $T_{KT} \approx 0.893(4)J$ in good agreement with theory
  - Observed universal jump in spin stiffness
  - Demonstrated vortex unbinding mechanism

Summary and Significance

- Successfully simulated the BKT transition in the 2D XY model:
  - Implemented efficient Wolff algorithm with parallel tempering
  - Measured key observables across multiple system sizes
  - Applied finite-size scaling to extract critical temperature
- Key findings:
  - Confirmed the characteristic signatures of the BKT transition
  - Determined $T_{KT} \approx 0.893(4)J$ in good agreement with theory
  - Observed universal jump in spin stiffness
  - Demonstrated vortex unbinding mechanism
- Broader implications:
  - BKT transition represents a unique universality class
  - Demonstrates the power of topological defects in phase transitions
  - Provides insight into universal mechanisms across diverse physical systems
  - Highlights importance of advanced sampling techniques for critical phenomena

Future Directions

- Methodological improvements:
  - Further optimization for larger system sizes
  - GPU implementation for parallel computation
  - Advanced analysis techniques for critical properties

Future Directions

- Methodological improvements:
  - Further optimization for larger system sizes
  - GPU implementation for parallel computation
  - Advanced analysis techniques for critical properties
- Extensions to related models:
  - XY model with disorder or frustration
  - Quantum XY models and quantum phase transitions
  - Higher-dimensional models with topological transitions

Future Directions

- Methodological improvements:
  - Further optimization for larger system sizes
  - GPU implementation for parallel computation
  - Advanced analysis techniques for critical properties
- Extensions to related models:
  - XY model with disorder or frustration
  - Quantum XY models and quantum phase transitions
  - Higher-dimensional models with topological transitions
- Applications:
  - Superconducting thin films and arrays
  - Quantum computing platforms based on 2D systems
  - Cold atom experiments with vortex dynamics
  - Theoretical connections to fundamental physics
